MAIN MODULE

main.broadcast_presence()

Broadcast presence and local files on the network.

main.command_line()

Interactive command line for user input to manage the P2P file sharing. This function provides a simple command line interface for users to list files, view peers, request files, or exit the application.

main.download_chunk(*filename, chunk_num, owners, temp_dir, download_success*)

Try to download a single chunk from any available owner.

main.download_file(*filename*)

Download a file chunk-by-chunk from multiple peers, assuming they have all chunks.

main.get_my_files()

Get a list of available files and their total number of chunks and their full SHA-256 hash.

main.handle_client(*conn, addr*)

Handle incoming file or chunk requests from peers.

main.list_files()

List all available files across all peers, based on their hash, excluding own files (by hash).

main.listen_for_peers()

Listen for incoming peer discovery messages and update peer file lists.

main.serve_files()

Serve files to peers that request them. This function listens for incoming TCP connections on a specified port, accepts file requests, and sends the requested files in chunks. It runs in a separate thread to allow concurrent file serving.

main.sha256sum(*path*)

Calculate the SHA-256 checksum of a file. This function reads a file in chunks and computes its SHA-256 hash. It is used to verify file integrity after download.

2.1 conf module

command to generate documentation:

```
sphinx-apidoc -f -o ./source ./ make make latexpdf
```
